1. Introduction

CLIF is a component-oriented software framework written in Java, designed for load testing purposes of any kind of target system. By load testing, we mean generating traffic on a System Under Test in order to measure its performance, typically in terms of request response time or throughput, and assess its scalability and limits, while observing the computing resources usage.

Basically, CLIF offers the following features:

- deployment, remote control and monitoring of distributed load injectors;
- deployment, remote control and monitoring of distributed probes;
- final collection of measurements produced by these distributed probes and load injectors.

Analysis tools for these measurements will be provided as soon as possible. For the time being, all measurements are available as CSV (comma separated values)-formatted text files.

Thanks to its component-based framework approach, CLIF is easily customizable and extensible to particular needs, for example, in terms of specific injectors and probes, definition of load generation scenarios, storage of measurements, user (tester) skills, integration to a test management platform, etc. For instance, user interfaces are available as command-line tools, Java Swing-based GUI and Eclipse-based GUI.

See installation manual for CLIF installation.
2. Key concepts

- **blade**
  an active component that can be deployed within a CLIF application, under control of the supervisor component, that provides statistical information about its execution (for monitoring purpose), and produce results stored by the storage component. Blades exist either as load injectors or probes.

- **CLIF application**
  set of deployed components making it possible to run a test. A CLIF application is a distributed component holding as sub-components: one supervisor, one storage, and an arbitrary number of probes and load injectors (aka blades).

- **CLIF server**
  a JVM with a bootstrap component that will locally handle blade deployment requests from the supervisor. In other words, one must run a CLIF server on a given computer in order to be able to deploy load injectors and probes. CLIF server have a name. They register themselves in the Registry with this name in order to be found by the deployment process.

- **code server**
  the code server is responsible for delivering Java byte-code and resource files on demand during the deployment process. This is achieved through a socket server with a specific protocol. As of current version, files greater then 2GB cannot be transfered.

- **collect, collection**
  action of getting all measurements, possibly disseminated through the blades by the storage proxy feature, into the storage component. Collection should not occur before a test is terminated.

- **deployment**
  local or remote instantiation of load injectors and probes (aka blades). During this process, Java byte-code and resource files may be loaded from the code server, through the network, and to the target JVM of the blade being deployed.

- **load injector**
  a component that conforms to the blade component type, whose activity consists in generating traffic on an arbitrary SUT, using arbitrary protocols, according to an arbitrary scenario.

- **probe**
  a component that conforms to the blade component type, whose activity consists in measuring the usage of an arbitrary computing resource. Probes may be deployed at the SUT's side, in order to better analyze and understand its performance, as well as at the load injectors' side, to check that they are performing all right (since saturating injectors may result in unreliable measurements or violated load scenarios).

- **(load) scenario**
  optional concept referring to the way a single load injector generates traffic, for instance by emulating the load of a variable number of users performing a variety of requests on the SUT. In other words, a scenario defines both shape and content of the traffic generated by a load injector.

- **Storage**
  centralized component for storing measurements produced by load injectors and probes (aka blades). The storage component is typically associated to a storage proxy feature supported by each blade.
• Storage proxy
  local buffering of measurements feature provided by blades in order to avoid flooding the network and the storage component, which could also disturb the test and spoil measurements.

• Supervisor or supervision console
  component responsible for controlling and monitoring of a test execution.

• System under test (SUT)
  an arbitrary system one wants to assess the performance of. It is typically composed of one or several computers, networks, etc. It has to be reachable, either directly or indirectly via some gateway, native library or any wrapping mechanism, from the Java Virtual Machine where CLIF servers are running.

• Registry
  a distributed naming service used by the deployment process to lookup CLIF servers and deploy load injectors and probes.

• Test (execution)
  execution (shot) of an already deployed test plan. A test ends under 3 possible conditions: completed, manually stopped or self-aborted.

• Test plan
  specifies a set of distributed load injectors and probes, including their instantiation arguments and the name of the CLIF servers where they must be deployed.
3. Registry

3.1. Rationale
CLIF servers are necessary to deploy any test plan, since they host load injectors and probes. CLIF servers are designated by a name, which is registered in a Registry. In order to run, CLIF servers must be able to find this Registry, which implies:

1. that the Registry must be running before a CLIF server can be launched;
2. that parameters must be given to tell the CLIF servers where to find the Registry and register themselves.

3.2. Running a Registry
There are three ways of starting a Registry: running the Java Swing console GUI (section 8), using the Eclipse-based console GUI (section 7), or using the appropriate command (section 9).
4. CLIF servers

4.1. Rationale

CLIF servers are necessary to deploy any test plan, since they host load injectors and probes. CLIF servers are designated by a name, which is registered in a Registry. In order to run, CLIF servers must be able to find this Registry, which implies that:

- the Registry must be running before a CLIF server can be launched;
- parameters must be given to tell the CLIF servers where to find the Registry and register themselves.

4.2. Configuring and running a CLIF server

A CLIF server requires a CLIF runtime environment, providing the CLIF command-line interface, such as the CLIF server or the CLIF Swing console. Refer to commands described by subsections 9.2 and 9.4 for details about configuring CLIF and running a CLIF server.

For more information, refer to the appendix on System properties in Appendix page 35.
5. Probes

5.1. Rationale

When load testing, it is often a good idea to check the usage of computing resources, both at the SUT side and the injectors' side. For instance, one may imagine system probes measuring CPU usage percentage, memory consumption, network bandwidth, etc. But other probes may be imagined that measure the size of a request queue length, a cache usage, or any activity data of any kind of middleware/software element involved in the SUT.

With CLIF, you may include probes in a test plan, as a complement to load injectors. Probes are supposed to have their own activity, typically (but not necessarily) consisting in polling a resource to measure its usage. All measurements are available from the Storage component once the test execution is over and the collection process has completed, while statistical values may be retrieved by the supervision console for monitoring purpose during test execution, directly from the probe. These statistical values are moving statistics computing on the period between two consecutive retrievals.

5.2. Available probes

Probes delivered with CLIF all consist in a periodic measure of the resource. They all take two arguments that must be specified in the test plan: the polling period (in milliseconds) and the execution duration (in seconds). Although probes start measuring once initialized for convenience, this execution time is counted once actually running (i.e. started and not suspended). When terminated, no measure is performed anymore.

To set a probe in a test plan:

- enter its family name as the “class name” information field;
- select the “probe” type;
- select the CLIF server where to deploy this probe, making sure that the target CLIF server actually runs on a computing environment (hardware, operating system or whatever) that is compatible with the probe family (see table below);
- enter the specific argument line, as explained hereafter.

Probes are specifically implemented for a variety of operating systems and architectures:

- Linux,
- FreeBSD,
- Mac OS X®,
- Windows®,
- Solaris®,
- AIX®,
- HP-UX
### 5.2.1. cpu probe

<table>
<thead>
<tr>
<th>family/class name</th>
<th>cpu</th>
</tr>
</thead>
<tbody>
<tr>
<td>measurements</td>
<td>• %CPU</td>
</tr>
<tr>
<td></td>
<td>• %CPU user</td>
</tr>
<tr>
<td></td>
<td>• %CPU kernel</td>
</tr>
<tr>
<td>alarms</td>
<td>none</td>
</tr>
<tr>
<td>2 arguments</td>
<td>polling period (ms), execution duration (s)</td>
</tr>
<tr>
<td></td>
<td>Example: 1000 60</td>
</tr>
</tbody>
</table>

### 5.2.2. disk probe

<table>
<thead>
<tr>
<th>family/class name</th>
<th>disk</th>
</tr>
</thead>
<tbody>
<tr>
<td>measurements</td>
<td>• issued reads</td>
</tr>
<tr>
<td></td>
<td>• read throughput (kBytes/s)</td>
</tr>
<tr>
<td></td>
<td>• issued writes</td>
</tr>
<tr>
<td></td>
<td>• write throughput (kBytes/s)</td>
</tr>
<tr>
<td></td>
<td>• IO time (micros)</td>
</tr>
<tr>
<td></td>
<td>• queue</td>

<tr>
<td></td>
<td>Example: 1000 60 /usr/local (Linux/Unix)</td>
</tr>
<tr>
<td></td>
<td>1000 60 C:\ (Windows)</td>
</tr>
</tbody>
</table>

See subsection 9.19 to get the list of available partitions' mount points on a particular host. This list is also returned by the error message when the given mount point is not correct.
### 5.2.3. memory probe

<table>
<thead>
<tr>
<th>family/class name</th>
<th>memory</th>
</tr>
</thead>
<tbody>
<tr>
<td>measurements</td>
<td>• % used ram</td>
</tr>
<tr>
<td></td>
<td>• used ram (MB)</td>
</tr>
<tr>
<td></td>
<td>• free ram (MB)</td>
</tr>
<tr>
<td></td>
<td>• free swap (MB)</td>
</tr>
<tr>
<td></td>
<td>• % used swap</td>
</tr>
<tr>
<td></td>
<td>• used swap (MB)</td>
</tr>
<tr>
<td>alarms</td>
<td>none</td>
</tr>
<tr>
<td>2 arguments</td>
<td>polling period (ms), execution duration (s)</td>
</tr>
<tr>
<td></td>
<td>Example: 1000 60</td>
</tr>
</tbody>
</table>
5.2.4. network probe

<table>
<thead>
<tr>
<th>family/class name</th>
<th>network</th>
</tr>
</thead>
</table>
| measurements      | • receive throughput (bit/s)  
|                   | • packets received  
|                   | • transmit throughput (bit/s)  
|                   | • packets transmitted  
|                   | • receive errors  
|                   | • receive overruns  
|                   | • receive drops  
|                   | • transmit errors  
|                   | • transmit overruns  
|                   | • transmit drops  
|                   | • transmit collisions |
| alarms            | none |

3 arguments polling period (ms), execution duration (s), network interface identifier At your own convenience, the network interface identifier may be one of the followings:

- *the network interface name*. It is easy to know on Linux/Unix from the output of command `ifconfig`. It is not directly available on Windows, unless using the CLIF utility described at subsection 9.19.
- *the network interface's IP address* - always easy to know on any system, for example, from the output of command `ifconfig` on Linux/Unix, or command `ipconfig` on Windows. The drawback is that this address may change from one system boot to another when the network interface configuration is not static (use of DHCP).
- *the network interface description*. It is the same as the network interface name on Linux/Unix. On Windows, the description is given by the system command `ipconfig /all`, but take care to *discard all white space characters*.

In any case, CLIF provides a utility to get the list of available network interfaces, with their name, IP address and description, on a particular host (refer to subsection 9.19). This list is also returned by the error message when the given network interface identifier is not correct.

Examples:

- 1000 60 eth0 *(Linux)*
- 1000 60 192.168.1.1
- 1000 60 BroadcomNetXtreme57xxGigabitController *(Windows)*
### 5.2.5. jvm probe

<table>
<thead>
<tr>
<th>family/class name</th>
<th>jvm</th>
</tr>
</thead>
</table>
| measurements      | • free memory (MB)  
|                   | • used memory %  
|                   | • free usable memory % |
| alarms            | An alarm with severity level “Info” is generated on each JVM garbage collection. |
| 2 arguments       | polling period (ms), execution duration (s)  
|                   | Example: 1000  60 |
| notes             | This probe must be deployed in the JVM to monitor, which involves installing and integrating a CLIF server to the JVM(s) of the system under test.  
|                   | In certain conditions, some garbage collection alarms may be missed.  
|                   | This probe is system-independent. |
5.2.6. jmx_jvm probe

<table>
<thead>
<tr>
<th>family/class name</th>
<th>jmx_jvm</th>
</tr>
</thead>
</table>
| measurements      | • free memory (MB)  
                  | • used memory %  
                  | • free usable memory % |
| alarms            | An alarm with severity level “Warning” is generated when the connection with the JMX agent of the target JVM could not be established. |
| 3 arguments       | polling period (ms), execution duration (s), configuration file name |

The configuration file must set these properties:

```plaintext
# username and password used for the JMX connection
server.user.name =
server.user.password =
# connection parameters to the MBean server
server.host.name =
server.host.port =
server.connection.protocol = rmi
server.jmx.connection.jndiroot = /jndi/iiop://
server.jmx.protocol_provider_package = com.sun.jmx.remote.protocol
server.jmx.location =
server.jmx.mbeanservername =
```

Refer to the documentation of your Java runtime to find out how to activate and contact its JMX agent.

Example: 1000 60 jonasjvm.props

with the following content for file jonasjvm.props:

```plaintext
# WARNING : activate first jvm jmx connection by adding option
# -Dcom.sun.management.jmxremote to JONAS_OPTS
server.host.name=target JVM host
server.host.port=1099
server.connection.protocol=rmi
server.jmx.connection.jndiroot=/jndi/rmi://
server.jmx.protocol_provider_package=com.sun.jmx.remote.protocol
server.jmx.location=
server.jmx.mbeanservername=jrmpconnector_jonas
```

notes

This probe is a “remote” probe in that it may be deployed anywhere, and remotely interrogates the target JVM. The advantage is that it does not require to install and integrate a CLIF runtime to the target system. The drawback is that it produces some network traffic during test executions (although it should be a small traffic).

This probe is system-independent but is only able to monitor a Sun/Oracle JVM.
### 5.2.7. rtp probe

<table>
<thead>
<tr>
<th>family/class name</th>
<th>rtp</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>measurements</strong></td>
<td></td>
</tr>
<tr>
<td>• number of packets per second</td>
<td></td>
</tr>
<tr>
<td>• cumulative number of packets lost</td>
<td></td>
</tr>
<tr>
<td>• minimum time jitter (ms)</td>
<td></td>
</tr>
<tr>
<td>• maximum time jitter (ms)</td>
<td></td>
</tr>
<tr>
<td>• average time jitter (ms)</td>
<td></td>
</tr>
<tr>
<td>• standard deviation of time jitter (ms)</td>
<td></td>
</tr>
<tr>
<td>• number of jumps per second</td>
<td></td>
</tr>
<tr>
<td>• number of inversions per second</td>
<td></td>
</tr>
<tr>
<td><strong>alarms</strong></td>
<td>none</td>
</tr>
<tr>
<td><strong>arguments</strong></td>
<td>polling period (ms), execution duration (s), port or port range to monitor</td>
</tr>
<tr>
<td>Examples:</td>
<td></td>
</tr>
<tr>
<td>• 1000 60 40000-40002 monitor ports 40000 to 40002</td>
<td></td>
</tr>
<tr>
<td>• 1000 60 40000 monitor port 40000</td>
<td></td>
</tr>
<tr>
<td>• 1000 60 40000-40004/2 monitor ports 40000, 40002, 40004</td>
<td></td>
</tr>
<tr>
<td><strong>note</strong></td>
<td>This probe is system-independent</td>
</tr>
</tbody>
</table>
6. Load injectors and ISAC

6.1. Rationale
Load injectors are set in a CLIF test plan in order to generate traffic on the SUT. With CLIF, you may use and imagine any kind of way to define and execute your load scenarios, on any kind of SUT. You may even mix a variety of load injectors in the same test plan. This is the reason why you must set a class name for each load injector you define in a test plan, and set an arbitrary line of arguments, specifically to the actual load injector you use. Fortunately for non-programmers, CLIF comes with the ISAC extension in order to provide an easy, powerful and user-friendly way to define load scenarios. Luckily for Java programmers, they may also define their own load injectors.

6.2. ISAC is a Scenario Architecture for CLIF
With ISAC, testers are given a way to define load scenarios by combining:

- definitions of elementary behaviors, typically representing users;
- optional definitions of load profiles setting the population (i.e. the number of active instances) of each behavior as a function of time.

6.2.1. behaviors
An ISAC behavior basically consists in a sequence of actions (requests) on the SUT interlaced with delays (think times). It may be enriched with the following constructs:

- conditional loop: while <condition>
- conditional branching: if <condition> then <true_branch> else <false_branch>
- probabilistic branching: nchoice choice<weight_1, branch_1> choice<weight_2, branch_2> ... choice<weight_n, branch_n>
  where weight_i is an integer representing the chance of executing branch_i (in other words, the probability of executing branch_i equals weight_i divided by \( \sum \) weight_j)
- preemptive condition: preemptive <condition, branch>
  program <branch> will exit as soon as <condition> is false (this condition is actually evaluated before executing each instruction in the branch)

6.2.2. load profiles
Load profiles enables predefining how the population of each behavior will evolve, by setting the number of active instances according to time. A load profile is a sequence of lines or squares. For each load profile, a flag states if active instances shall be stopped to enforce a decrease of the population, or if the extra behaviors shall complete in a kind of a “lazy” approach.

6.2.3. ISAC plug-ins
A behavior can be understood as a logic definition, a kind of a skeleton. In order to actually generate traffic on the SUT, this skeleton must be associated to one or more ISAC plug-ins. Plug-ins are external Java libraries, that are responsible for:
• performing actions (i.e. generating requests) on the SUT, whose response times will be measured, using and managing specific protocols (e.g. HTTP, DNS, JDBC, TCP/IP, DHCP, SIP, LDAP or whatever);
• providing conditions used by the behaviors' conditional statements (if-then-else, while, preemptive);
• providing timers to implement delays (think time), for example with specific random distributions or computed in some arbitrary way;
• providing ad hoc controls for the plug-in itself (e.g. to change some settings);
• providing support for external data provisioning (e.g. a database of product references or a file containing identifier-password pairs for some user accounts), used as parameters by the behaviors.

6.2.4. Writing an ISAC scenario

ISAC scenarios are stored in and read from XML files, with extension ".xis" (standing for XML Isac Scenario). An ISAC scenario holds three main sections:

1. a section for plug-in imports, where default/initialization parameters can be set. A plug-in may be imported more than once if necessary: for each imported plug-in, each instance of each behavior will hold a sort of private context (called session object). Each imported plug-in is designated via a unique identifier.

2. a section for behaviors definition. All actions (aka samples), conditions (aka tests), controls and delays (aka timers) must refer to an imported plug-in using its identifier. For each call to the plug-in, specific parameter strings may be set. Those strings may hold variables: when the pattern \${plugin-identifier:key} is found, it is replaced at runtime by a value that the designated plug-in associates with the provided key string. The designated plug-in must be a "data provider" type plug-in, and the interpretation of the key depends on it (refer to the documentation of the data provider plug-in).

3. an optional section for load profiles, with (at most) one profile per behavior.

The most user-friendly way to edit a scenario is to use the Eclipse-based ISAC graphical editor (see section 7). The alternative is to use an XML or text editor (the DTD of ISAC scenarios is given in appendix page 41).

6.2.5. Recording an ISAC scenario for HTTP

In order to make realistic scenarios corresponding to real users behaviors, web interactions (sessions) can be recorded in ISAC scenario. It consists in using a recording HTTP proxy called MaxQ, available from the download section of CLIF's forge (http://forge.ow2.org/projects/clif/), as well as from tigris.org open source community (http://maxq.tigris.org/). MasQ will generate an ISAC scenario with all performed HTTP requests, and possibly all think times elapsed between two consecutive requests.

This Java tool may be used either as a standalone tool, or through an Eclipse wizard embedded in CLIF’s Eclipse-based console (see section 7).

To record an ISAC scenario with the standalone version of MaxQ:
1. You have to edit the maxq.properties file and to choose which timer will be used during the injection (ConstantTimer and RandomTimer are available). You can also specify on which port starts MaxQ. By default, it starts on the port 8090.

2. You have to configure your web browser to go through a proxy for http requests.

3. Then you have to click on "File" -> "New" -> "ISAC scenario". At this point, the proxy is started but doesn't record ISAC scenario yet: it works as a transparent proxy.

4. Click on "Test" -> "Start Recording". Now, all requests going from the web browser to a server will be stored in the ISAC scenario.

5. At the end of the web session, click on "Test" -> "Stop Recording". A pop-up appears to select a name and a destination to save the file. Give a name with the extension ".xis". Then save.

Now you have a scenario corresponding to a user behavior. You can import it in your Clif Console to edit the load profile in order to replay it on a large scale.

6.2.6. Deploying and executing an ISAC scenario

Remember that a scenario is local to each load injector. When editing your test plan, the key idea is to use the ISAC execution engine as a load injector, and to set the test plan file as argument:

- class name: IsacRunner
- arguments: myScenario.xis

Your code server path should include the directory where your scenario file is, in order to benefit from the automatic remote loading of the scenario file by every remote ISAC execution engine you may have defined in your test plan.

A number of the execution engine's parameters may be modified, including at runtime:

- about the engine itself (size of the thread pool, polling period for load profile management, tolerance on deadlines - see appendix page 44);
- about the active scenario, in particular the number of active instances (population) of each behavior.

ISAC scenarios end on completion (load profiles time have elapsed), failure (abort), or manual stop. As soon as at least one behavior population has been manually set, or when no load profile is defined for any behavior, the scenario must be manually stopped.

6.3. Synchronization pseudo-injector

6.3.1. Rationale

A test plan may include several load injectors which require some global synchronization between each other. When using ISAC scenarios, for example, virtual users belonging to different scenarios, possibly distributed among different CLIF servers, may need to synchronize with each other. ISAC provides a synchronization plug-in dedicated to this kind of feature.
6.3.2. Usage

In order to support global, distributed synchronization, a test plan must include (at least) one synchronization pseudo-injector:

- **class name**: Synchro
- **arguments**: synchronization_domain_name duration_in_seconds \[lock_1=n_1 \ldots\]

The first argument is a synchronization domain name. This name may be freely chosen, but it must be unique in your test plan. This name will be necessary for your scenarios (e.g. through the synchronization ISAC plug-in) to connect to the synchronization server embedded in the pseudo-injector.

The second argument is the execution duration, in seconds. This allows for an autonomous termination of the synchronization pseudo-injector, with the completed status. Note that, even when completion is reached, the synchronization features are still operational. In other words, it works still after the duration has elapsed.

Subsequent arguments are optional. They allow for declaring one or several predefined *rendez-vous*, specifying the minimum number of notifications that must be received by the named lock before releasing it. Refer to the synchronization tool documentation (e.g. the synchronization ISAC plug-in's help) for details about this feature.

6.3.3. Alarms

The Synchro pseudo-injector generates an alarm on the first notification of each lock. This alarm has the following fields:

- **date**: elapsed time since the test initialization (in milliseconds)
- **severity level**: 0 (INFO)
- **message**: first notification of lock *lock_name*
7. Eclipse-based graphical user interface

7.1. Introduction

CLIF comes with an Eclipse-based Graphical User Interface. This GUI has 4 functions:

• a CLIF console for test deployment, execution and monitoring, including a test plan editor;
• a graphical editor for ISAC scenarios;
• a programming environment for ISAC plug-ins;
• a reporting environment¹.

To install and run the Eclipse-based Graphical user interface, see the Install Manual.

7.2. Run CLIF registry

Connection to the CLIF registry is updated on each test plan deployment or edition, according to the registry settings of the test plan's project (see the CLIF project settings in the Eclipse Preferences window, or the project's clif.props file). So you might run a standalone registry outside of the console, anywhere and rerun it anytime between two consecutive deployments.

Moreover, the console automatically runs a registry whenever it can't connect to the specified registry, using the specified registry port number. You can actually rely on this feature as a simple way to have a registry running without caring of starting it. The consequence is just that you have to run your CLIF servers after the console. This registry can't be stopped unless you quit the console, but still you can switch to any other registry by changing the settings.

¹ currently as a preliminary version to be further completed by the CLIF team.
7.3. Test plan edition
CLIF user manual guide

7.4. ISAC scenario edition

Please refer to the help section for the ISAC editor available from the Help menu. Refer also to section for information about ISAC.
7.5. test deployment and execution

Please refer to the help section available from the Help menu.
8. Java Swing-based graphical user interface

8.1. Introduction

CLIF comes with a Java/Swing-based Graphical User Interface. This GUI consists of a console for test deployment, execution and monitoring, including a test plan editor. It also provides an analysis tool to help produce test reports.

Compared to the Eclipse RCP-based console (see section 7), the Swing-based console has the advantage of light-weight, simplicity and operating-system independence. On the negative side, its simplicity springs from a reduced set of features. In particular, it does not provide an ISAC scenario editor nor an ISAC plug-ins creation wizard. As far as the test results analysis is concerned, the consoles provide different tools that suit different needs. The one provided by the Swing console is probably more straightforward to use, and rapidly gives graphical views, while the one provided by the Eclipse console is suited to the creation of long reports based on well-structured report templates. Of course, once a test has been run, any analysis tool may be used regardlessly of the user interface that has been used to run the test.

Note that the Swing console is actually embedded in the CLIF Eclipse-RCP distribution, since it provides the so-called CLIF runtime environment directory, located in the console plug-in path, i.e. something like `plugins/org.ow2.clif.console.plugin_x.x.x/`.

To install and run the Java Swing-based graphical user interface, see the Installation Manual.

8.2. Run CLIF registry

The GUI first tries to connect to a registry according to the registry configuration found in file `etc/clif.props`. If it can't connect, it creates a registry.
8.3. Test plan edition table

A test plan defines the probes and the injectors to be used, with their parameters, and where to deploy them. Remember that injectors and probes are uniformly designated as "blades". The table in the upper part is the test plan editor. Note that the bottom part (monitoring) is hidden as long as the test is not initialized. Note also that the test plan is not editable when the monitoring area is shown.

Each row of the test plan table defines a blade configuration, through 6 columns:

- **Blade id** is a unique identifier for the injector or probe to be deployed. A default id is automatically set when adding a new blade, but it may be freely changed by the user as long as it remains unique within current test plan;
- **Server** offers a choice between available CLIF servers, where the blade is to be deployed. The list of CLIF servers may be updated using option "Window > Refresh server list";
- **Role** specifies whether the blade is a probe or an injector;
- **Blade class** is where the user sets:
  – either the Java class to be instantiated as a load injector (fully qualified name, without trailing .class extension - see section 6),
  – or a family name in case of a probe (see section 5);
- **Blade argument** is an argument line that will be passed to the new blade instance at deployment time;
- **Comment** is an arbitrary user comment line.
The last column **State** is not editable. It shows state information about the blade (undeployed, deploying, deployed, starting, running, stopping, suspending, resuming, completed, aborted...).

Test plans may be saved and restored using options in the File menu.

### 8.4. Performance and resource usage monitoring

As soon as the test plan is deployed and initialized, the monitoring area pops up in the test plan window's bottom part. This area holds a set of tabbed panels:

- one for all injectors
- one for each probe family

For each panel, the user may set the monitoring time-frame, the polling period, and start or stop the monitoring process. Moreover, a check-box table at the left side of each panel makes it possible to selectively disable or enable the collect and display of monitoring data, for each blade.

### 8.5. File Menu

From this menu, the user can find options for saving and loading a test plan. This menu also holds the "Quit" option to exit from CLIF console, which also terminates the registry where CLIF servers are registered. As a result, whenever you terminate a CLIF console, any remaining CLIF server will then become unreachable - you may stop these unreachable CLIF servers manually. Running the CLIF console again will create a new, empty registry, and then you may launch new CLIF servers. The user may not quit the console while a test is running (other wise, the behavior is undefined).

### 8.6. Test plan menu

This menu holds test deployment and control commands. There are 2 subsets of options:

- the first set holds test plan definition and deployment commands
  - option **Refresh server list** updates the list of available CLIF servers,
  - option **Edit** switches to test plan edition mode, when enabled (i.e. when not already in edition mode, and when no deployed test is currently running),
  - option **Deploy** deploys the probes and injectors defined by current test plan
- the second set holds test control commands
  - command **initialize** initializes all the blades so that they are actually ready to start;
  - commands **start, suspend, resume** and **stop** respectively start, suspend, resume and stop the execution of all blades;
  - command **collect** tells the storage system to collect all test data from the blades (the actual effect of this command fully depends on the Storage component). This option may be used only after a test run. Collecting more than once after a test run has no effect; collecting is not mandatory, which means that the user may not collect data if s/he is not interested in the test results.

### 8.7. Tools menu

This menu displays on/off additional tools:

8.7.1. Basic analyzer

The Basic analyzer tool provides a very simple analysis tool sample. It must be used once at least one test execution is complete, since it needs to get measures from one test execution.

8.7.2. Quick graphical analyzer

The Quick Graphical Analyzer tool intends to provide a powerful and efficient tool to fulfill test analysis and reporting needs. It is also embedded in the Eclipse-based console. This tool is currently under development, but some basic features may be used already. Documentation will be detailed as the tool development is progressing.

Report principle

A report is a set of pages. Each page holds:

• a number of data sets, built from CLIF’s measures collected after a test execution, according to a number of possible filters;
• for each dataset, an optional section of statistical values computed from one specific metric;
• for each statistics section, an optional drawing of the selected metric in a graph section;
• a single graph section, where possible dataset drawings are superimposed.

Datasets

There are three types of dataset (see File menu).

The basic type is the Simple Dataset. It represents a set of measures of a given type produced by a given load injector or a probe, from a given test execution. For example: the alarm events from one JVM probe of one test execution, or the action events from one load injector of one test execution. A number of selection filters may be used to keep only the measures of interest. For example, keep only requests of a given type or with a response time less than a given threshold. Filtering on dates is also possible to restrict analysis to a sub-period of the test execution.

The Multiple Dataset offers an efficient way to select a given event type produced by several load injectors or probes with the same filters. It is equivalent to creating as many simple datasets as chosen injectors or probes, but in a single operation. Further optional statistical analysis and drawing will be also defined once for all injectors and probes. Typical examples: create a multiple dataset including every CPU probe of a given test execution, in order to get per-CPU analysis and drawing superimposed on the same graph, or a given CPU probe in several test executions to compare CPU usage.

The Aggregate Dataset enables to create a kind of simple dataset containing the full set of events of a given type coming from several load injectors or probes measures. Typical usage: when using several load injectors in a test, to get the global response time and throughput in the analysis and drawings.

8.8. Help menu

This menu holds a single "About..." option, which displays CLIF version and compilation information. This information is important to get and mention whenever you report a problem using CLIF.
9. Command line user interface

9.1. Introduction

Once you have created a test plan file (either using the Eclipse-based or the Java Swing-based GUI, or editing a text file with the appropriate syntax), you may deploy and run tests using the following commands. Those commands are packaged as Apache ant targets defined in the build.xml file available at CLIF runtime environment's root.

Prior to any command, one Registry must be run for the whole test. It will be used by every command to register or lookup the components of the deployed test plan (aka CLIF application): injectors, probes, supervisor, storage.

Some of these commands apply either to every probe and injector of a deployed test plan, or to a subset of them. In the latter case, you must specify an extra argument to give the list of the target injectors and probes identifiers (so-called blade identifier, as defined in the test plan):

- `Dblades.id=id1:id2:...idn`. Note that separately managing probes and injectors can become tricky in big test plans... A typical usage of CLIF may not need this feature, and you would only make use of the commands' default global scope.

Note that authorized commands depend on the state of the injectors and probes. Refer to the appendices of the Developer Manual for details about the blade life-cycle.

The typical sequence of basic commands is the following: `config - registry - server - launch`. In the special case of a test plan using only the default CLIF server “local host”, only the `launch` command is necessary.

9.2. Configure the CLIF environment: `config`

```bash
ant [-Dregistry.host=myRegHost] [-Dregistry.port=1234]
    [-Dcodeserver.host=myCodeServerHost] [-Dcodeserver.port=135]
    [-Dcodeserver.path=myCodesererPath] config
```

This command is a helper to update CLIF's configuration file located in `etc/config.props`. The extension name of this configuration file is a bit misleading: although it actually defines Java properties, it also defines, more generally, JVM options, and it does not follow the common Java property file syntax. For this reason, it is recommended to use this helper command, which is sufficient for a common usage of CLIF. However, setting extra properties or adding custom JVM options will require to edit this file with a text editor. Refer to appendix page 35 to get the full list of CLIF customization properties.

This command is either interactive or non-interactive: when option `-Dregistry.host` is set in the command line, no user interaction is performed, while the user is prompted for a registry host value otherwise. In both cases, all other options are automatically set to their default values, which should be correct in common cases.

The CLIF configuration step must be performed on each CLIF runtime environment involved in a test plan deployment, before any other command. This includes the target CLIF servers, as well as the CLIF runtime from which you deploy test plans. When deploying with the Eclipse-based console, configuration is achieved through the GUI (see the CLIF properties of the test project).
Options:

-Dregistry.host=...: set the IP address or network name of the node where the registry is expected to be run. localhost is the initial value when no configuration is performed, but it only works when test plans are not be deployed over a network, but on the same node as the registry itself.

-Dregistry.port=...: set the TCP port number used by the CLIF registry. You may change the default value 1234 when it is not free or permitted on your registry node.

-Dcodeserver.host=...: set the IP address or network name of the node where the CLIF code server is expected to be run. The code server is automatically launched when you deploy a test plan, so that necessary resource files or even Java code can be transparently dispatched to all the CLIF servers involved in a distributed test plan. In common situations, you may run the test plan deployment on the same node as the registry. So, when this option is omitted, the config command assumes that the code server's address is the same as the registry's address. Then, you must set this option whenever you deploy a test plan from one node, while the registry is running on another node.

-Dcodeserver.port=...: set the TCP port number used by the code server. You may change the default value 1357 when it is not free or permitted on the node hosting the code server (the node you run the test plan deployment from).

-Dcodeserver.path=...: set the directories from where the code server should look for when CLIF servers ask for missing resource files or code when a test plan is being deployed. The default value is the current working directory (represented by "."). This option is useful only in the CLIF runtime environment from which test plans are deployed; CLIF servers do not use this parameter.

9.3. Run CLIF Registry: registry

ant registry

Runs a Registry on the local host. All CLIF servers that will be involved in the test plan the user is planning to deploy must then be launched with the right configuration. Refer to subsection 9.2 for details. This command never returns unless the Registry process is killed.

Note: Only one Registry shall be launched on a given host (further attempts will just fail), unless you install another CLIF runtime environment and configure it with a different registry port.

9.4. Run a CLIF server: server

ant [-Dserver.name=myClifServer1] server

Runs a CLIF server and registers it in the CLIF registry, either using current host name as server name, or using the provided name when option -Dserver.name is set. In either way, CLIF servers' names must match servers' names in the test plans to be deployed. Names are case-sensitive. A CLIF server can not be created without a reachable Registry.

This command never returns unless the CLIF server process is killed.

Notes:
9.5. Print the list of available CLIF servers: listservers

```
ant listservers
```

Prints the list of CLIF servers currently registered in the CLIF Registry.

9.6. Wait for registry and CLIF servers: waitservers

```
ant -Dtestplan.file=myTestPlan.ctp waitservers
```

Waits until the registry and all CLIF servers used in a given test plan file are ready. Note the default CLIF server named "local host" is not taken into account, since it is created by the deploy command. This command is typically called before the deploy or launch command, to avoid a deployment failure due to missing CLIF servers.

This command output lists the CLIF servers as soon as they are available. If you notice that a CLIF server is missing in the output, and that the command does not exit, then either this CLIF server was not successfully started, or it has erroneously registered in a different registry. In both cases, check the configuration of the faulty CLIF server and (re)start it.

9.7. Test plan deployment: deploy

```
ant -Dtestplan.name=name -Dtestplan.file=myTestPlan.ctp deploy
```

Deploys a new test plan (probes and injectors) as defined by a given test plan file. This deployed test plan is given a name that is further required for all others commands. When successful, this command does not return, and should not be manually terminated as long as you want to use the deployed test plan. The resulting process' role is similar to a (graphical) console's role, in that it contains the Supervisor and Storage components, as well as the code server.

9.8. Test initialization: init

```
ant -Dtestplan.name=name -Dtestrun.id=testId [-Dblades.id=id1:id2:...:idn] init
```

Initializes all probes and injectors in a deployed test plan, or just a subset of them when mentioned. The target deployed test plan is designated by its name (as set with deploy command). An identifier for this new test being initialized must be provided. This identifier will only be used to identify this test run, for instance when accessing to results.

9.9. Test execution start: start

```
ant -Dtestplan.name=name [-Dblades.id=id1:id2:...:idn] start
```

- when a CLIF server is killed, its name remains registered until the registry is restarted, or another CLIF server is started and registered with the same server name. Then, a test plan deployment may fail not only because a CLIF server name is missing in the registry, but also because the corresponding CLIF server is no longer alive.
- whenever the Registry is restarted, all registered CLIF servers must be restarted also in order to be reachable again.
- a default CLIF server, named “local host”, is created by the deployment command.
Starts probes and injectors of the given deployed test plan, or just a subset of them when mentioned. They must be initialized prior to this command.

9.10. Suspend test execution: suspend

```ant -Dtestplan.name=name [-Dblades.id=id1:id2:...:idn] suspend```

Suspends probes and injectors of the given deployed test plan, or just a subset of them when mentioned. They must be running (started or resumed) prior to this command.

9.11. Resume test execution: resume

```ant -Dtestplan.name=name [-Dblades.id=id1:id2:...:idn] resume```

Resumes probes and injectors of the given deployed test plan, or just a subset of them when mentioned. They must be suspended prior to this command.

9.12. Stop test execution: stop

```ant -Dtestplan.name=name [-Dblades.id=id1:id2:...:idn] stop```

Definitively and immediately (in a best effort sense) stops probes and injectors of the given deployed test plan, or just a subset of them when mentioned. Stopping is possible for both running and suspended probes/injectors, as well as right after initialization. Don't forget to use the collect command to gather all measurements to the local site. Once a test is stopped, the same deployed test plan may be initialized again to run another test.

9.13. Wait for a test execution to terminate: join

```ant -Dtestplan.name=name [-Dblades.id=id1:id2:...:idn] join```

Waits until the probes and injectors of the given deployed test plan, or just a subset of them when mentioned, terminate. Probes and injectors should be running to prevent this command from blocking forever.

```ant -Dtestplan.name=name [-Dblades.id=id1:id2:...:idn] collect```

Collects results generated by the probes and injectors of the given deployed test plan, or just a subset of them when mentioned. Collecting is optional, i.e. the user may not collect results s/he is not interested in. Injectors and probes must be terminated prior to this command.

9.15. Shortcut for full test execution process: run

```ant -Dtestplan.name=name -Dtestrun.id=testId [-Dblades.id=id1:...:idn] run```

Shortcut for init, start, join and collect on the probes and injectors of the given deployed test plan, or just a subset of them when mentioned.

9.16. Shortcut for full deployment and execution process: launch

```ant -Dtestplan.name=name -Dtestrun.id=testId -Dtestplan.file=myTestPlan.ctp launch```
Shortcut for deploy, init, start, join and collect on all probes and injectors of the given test plan. The command exits when the full process is complete. As a major difference with the use of target deploy that enables several consecutive runs on the same deployed test plan, here the test plan is deployed and executed only once.

9.17. Get specific runtime parameters of a probe or injector: params

ant -Dtestplan.name=name -Dblade.id=id params

Lists all parameters of a probe or injector that may be changed (including while running). These parameters and corresponding possible values are specific to the target probe or injector.

9.18. Change a runtime parameter of a probe or injector: change

ant -Dtestplan.name=name -Dblade.id=id -Dparam.name=param -Dparam.value=value change

Changes a parameter's value for a given injector or probe in a given deployed test plan.

ant -Dprobe.type=probeType probehelp

Prints a help message about the arguments that a probe of type probeType must be given when it is involved in a test plan. Existing probe types and their arguments are detailed in this documentation (see section 5.2), but this command is helpful for argument values that are not always straightforward to guess, like a network adapter name or a partition path.

9.20. Generate and print a quick statistical report: quickstats

ant [-Dreport.dir=reportdirectory] [-Dclif.quickstat.cleanfactor=f -Dclif.quickstat.cleanlimit=p] quickstats

Prints a statistical report for the latest test, for all requests from all load injectors, request type (aka action type) by request type, and also globally for all types of requests.

- reportdirectory is the root directory of tests measures (if different from the default one)
- for f and p, refer to Appendix A p.35 for explanations about both system properties.
10. Test results and measurements

CLIF tests gather the following data:

- test plan copy,
- Java system properties at test execution time for all probes and injectors,
- measurements from all probes and load injectors,
- life-cycle events for all probes and injectors,
- alarms generated by injectors or probes (if any).

As of current Storage component implementation, all these data are gathered in a hierarchy of CSV\(^1\)-files in a subdirectory of CLIF's runtime environment named "report" by default. This target directory may be changed with a system property (see appendix page 35).

Both the Eclipse RCP-based console (section 7) and the Java Swing-based console (section 8) provide graphical and statistical analysis tools.

---

\(^1\) Comma-Separated Values, a common text-based export format for spreadsheet programs. Each line of the CSV file contains an event (measure entry), and values hold by each event are separated by a comma.
CLIF user manual guide

11. Licenses

CLIF is open source software licensed under the GNU Lesser General Public License (LGPL).

CLIF comes with facilities including the following open source software libraries:

- **Jakarta commons HttpClient**, from the Apache Software Foundation, released under Apache License;
- **OpenLDAP** from the OpenLDAP Foundation, released under OpenLDAP Public License
- **Htmlparser from Source Forge**, released under LGPL license;
- **Eclipse** graphical user interface libraries and Rich Client Platform, released under Common Public License;
- **PostgreSQL JDBC driver**, released under BSD license;
- **DnsJava** for DNS injection support, released under BSD License;
- **JDOM** for XML parsing in ISAC, released with a specific license;
- **JavaMail** for IMAP load injection, released under Berkeley license.
**Appendix A: system properties**

A number of Java system properties are set in file `etc/clif.props` of CLIF runtime environment. This file is used by the helper ant targets provided in file `build.xml` located at the root of CLIF runtime environment. Should you need to use CLIF without ant, don't forget to set all these system properties when launching the appropriate class in your Java Virtual Machine.

System properties used by CLIF are listed in the table hereafter:

<table>
<thead>
<tr>
<th>system property</th>
<th>comment</th>
<th>default value in file etc/clif.props</th>
<th>default value in binary code</th>
</tr>
</thead>
<tbody>
<tr>
<td>java.security.policy</td>
<td>set Java security policy file</td>
<td>etc/java.policy</td>
<td>none</td>
</tr>
<tr>
<td>fractal.provider</td>
<td>set Fractal implementation</td>
<td>org.objectweb.frac tal.julia.Julia</td>
<td>none</td>
</tr>
<tr>
<td>fractal.registry.host</td>
<td>set hostname running FractalRMI registry. The registry is now integrated to the console (so the host is the console's host)</td>
<td>localhost</td>
<td></td>
</tr>
<tr>
<td>fractal.registry.port</td>
<td>set port number for the FractalRMI registry launched by the console.</td>
<td>1234</td>
<td></td>
</tr>
<tr>
<td>julia.config</td>
<td>using Julia as Fractal implementation, set Julia configuration file</td>
<td>etc/julia.cfg</td>
<td>none</td>
</tr>
<tr>
<td>julia.loader</td>
<td>using Julia as Fractal implementation, set class loader</td>
<td>org.objectweb.frac tal.julia.loader .DynamicLoader</td>
<td>none</td>
</tr>
<tr>
<td>clif.codeserver.port</td>
<td>set port number for class and resource server embedded in the console</td>
<td>1357</td>
<td>none</td>
</tr>
<tr>
<td>clif.codeserver.host</td>
<td>set host name for class and resource server embedded in the console</td>
<td>localhost</td>
<td>none</td>
</tr>
<tr>
<td>clif.codeserver.path</td>
<td>ordered set of directories where the codeserver may look for classes and resources it is asked for, separated by ; character. Note that, whatever the value of this property, classes and resources are first looked for in the jar files in lib/ext/ directory, and in the console's current directory. Absolute paths are used as is, while relative paths are interpreted from the root of CLIF's runtime environment.</td>
<td>examples/classes/ (just to make examples run)</td>
<td>none</td>
</tr>
</tbody>
</table>
### CLIF User Manual Guide

<table>
<thead>
<tr>
<th>system property</th>
<th>comment</th>
<th>default value in file etc/clif.props</th>
<th>default value in binary code</th>
</tr>
</thead>
<tbody>
<tr>
<td>clif.deploy.besteffort</td>
<td>When set to yes, true, on or 1 (case-insensitive), the deployment process discards from the test plan all blades that cannot be successfully deployed, for any reason (missing or mute CLIF server, blade failing to be deployed). Then, the resulting sub-test plan is regarded as successfully deployed as long as at least one injector or probe could be successfully deployed.</td>
<td>none</td>
<td>false</td>
</tr>
<tr>
<td>clif.deploy.retries</td>
<td>Number of retry attempts to reach a CLIF server for deploying new blades. This feature applies to CLIF servers that would be registered in the CLIF registry, but that would not be ready yet.</td>
<td>none</td>
<td>0</td>
</tr>
<tr>
<td>clif.deploy.retrydelay</td>
<td>Sleeping delay, in milliseconds, between two consecutive blade deployment attempts on a registered but unreachable CLIF server.</td>
<td>none</td>
<td>2000</td>
</tr>
<tr>
<td>clif.deploy.timeout</td>
<td>Maximum acceptable time, in milliseconds, waiting for a set of blades to be deployed on each CLIF server. When the time-out is reached for one CLIF server, all of its blades, as defined in the test plan, are discarded. This results in a test plan deployment failure, or not, according the &quot;best effort&quot; setting. Note: this duration shall be consistent with, and actually greater than, the number of deployment attempts multiplied by the delay between two consecutive attempts (see the &quot;retries&quot; settings). 0 means no time-out (i.e. deployment time is unlimited).</td>
<td>none</td>
<td>0</td>
</tr>
<tr>
<td>system property</td>
<td>comment</td>
<td>default value in file etc/clif.props</td>
<td>default value in binary code</td>

<tr>
<td>--------------------------</td>
<td>--------------------------------------------------------------------------</td>
<td>--------------------------------------</td>
<td>-----------------------------</td>
</tr>
<tr>
<td>clif.filestorage.clean</td>
<td>Sets the cleaning policy with regard to the conservation of test measurements. The &quot;none&quot; policy keeps all measurements of all tests. The &quot;auto&quot; policy discards all output from previous tests as soon as a new test is initialized.</td>
<td>&quot;none&quot;</td>
<td>&quot;none&quot;</td>
</tr>
<tr>
<td>clif.filestorage.delay_s</td>
<td>Sets the delay (in seconds) before the file-based storage system actually writes events after they are created. Typical value should be greater than the variation of response times to get events written in chronological order. However, this delay setting may be subsumed by the setting of maximum number of pending events (see property clif.filestorage.maxpending).</td>
<td>60</td>
<td>60</td>
</tr>
<tr>
<td>clif.filestorage.maxpending</td>
<td>Sets the maximum number of pending events, waiting to be written to file because they are younger than the write delay (see property clif.filestorage.delay_s). Whenever this threshold is overwhelmed, oldest pending events are written without waiting for the write delay. This may lead to chronologically unordered events in the file, but prevents from saturating the JVM's heap memory because of event buffering (especially for high event throughputs).</td>
<td>1000</td>
<td>1000</td>
</tr>
<tr>
<td>clif.filestorage.dir</td>
<td>Sets the file system directory to be created (if necessary) and used to store the generated measures. An absolute path is used as is, while a relative path is interpreted from the root of CLIF’s runtime environment.</td>
<td>none</td>
<td>report</td>
</tr>
<tr>
<td>system property</td>
<td>comment</td>
<td>default value in file etc/clif.props</td>
<td>default value in binary code</td>
</tr>
<tr>
<td>-----------------</td>
<td>---------</td>
<td>-------------------------------------</td>
<td>-----------------------------</td>

Other system properties may be useful for a variety of use cases (they are given in comments in file etc/clif.props.template):

- for remote Java debugging:
  -agentlib:jdwp=transport=dt_socket,address=8000,server=y,suspend=n
- for SSL certificates (for example for HTTPS support):
  -Djavax.net.ssl.trustStore=/path/to/keystore
  -Djavax.net.ssl.trustStorePassword=the_keystore_password
Appendix B: Class and resource files (remote) loading

Principle

When components are deployed in a CLIF server (probe, injector), the corresponding classes are automatically downloaded from the console if they are locally missing. Moreover, those components may require resource files (see webtest.urls file in webtest example, or helloworld.xls file in isac-helloworld example), which the user would rather not have to copy on every CLIF server. The content of these resource files can be remotely read via the console too.

This feature relies on a specific Java class loader and its associated system property clif.codeserver.path on the one hand, and on a so-called "code server" embedded in the console on the other hand.

Where classes and resource files are looked for?

The code server embedded in the console looks for the requested classes and resources successively in the following places:

- jar files in CLIF distribution's lib/ext/ directory where the console is running. Note: since the code server indexes the contents of all jar files in lib/ext/ at console start-up, all necessary jar files must be present before running the console;
- the console's current directory (which should be CLIF's root directory);
- the directories declared by clif.codeserver.path property, relative to the console's current directory.

See appendix on system properties page on User Manual for details on how to set the clif.codeserver.path property, and how to set the port number for the code server.

Appendix D: ISAC execution engine

The ISAC execution engine is the interpreter class for ISAC scenarios. When editing a test plan, just select the “injector” role and type IsacRunner in the “class” field. Then, fill the “arguments” field with the file name of the ISAC scenario you want to run. As a general advice, don't set the full path name but simply the file name, and add the directory where the scenario file resides to the code server path (see appendix p. 40). When using the Eclipse console, the file typically resides in the project directory.

The ISAC thread pool

The ISAC execution engine uses a pool of threads to run virtual users (aka behavior instances). When a virtual user is engaged in a think time, its execution thread is used to activate another virtual user. This way, the size of the thread pool is typically far smaller than the maximum of simultaneously running virtual users that is specified by the load profile. This pool has a default size that may be changed:

- before runtime:
  - either by setting system property clif.isac.threads
  - or by adding option threads=my_custom_pool_size in the “arguments” field;
- at runtime, by changing the value of parameter “threads”.

Millions of virtual users per execution engine can easily be reached. The issue is that the think times must be much greater than the response times in order to really support such a number of virtual users without violating the specified behaviors. The theoretical optimal thread pool size is:

\[
\text{optimal pool size} = \frac{\text{maximum number of virtual users} \times \text{average response time}}{\text{average think time} + \text{average response time}}
\]

The actual optimal pool size shall be a little greater to face possible transient variations of the global activity (when many virtual users simultaneously exit from a think time) and the overhead of context switching between virtual users. The default size (see appendix p. 35) may require to be adjusted to your particular test case. Of course, setting an over-sized pool of threads will waste computing resources and result in performance degradation.

Deadline violation alarms (Job delay)

When the execution engine becomes overloaded, a consequence is that virtual users’ think times become longer than specified. In other words, the deadline for performing the action next to the think time is violated. It is possible to get an alarm event when a given tolerance threshold is reached. This feature is enabled as soon as a positive value is set for this threshold, expressed in milliseconds. To set the threshold:

- before runtime:
  - either set system property clif.isac.jobdelay
  - or add option jobdelay=my_custom_threshold_in_ms to the “arguments” field;
- at runtime, by changing the value of parameter “jobdelay”.

Note that enabling this alarm results in a slight overhead in the execution engine functioning. Moreover, setting a small threshold value may result in a profusion of meaningless alarms: a small deadline violation from time to time does not necessarily mean the engine is overloaded. The
relevant threshold value depends a lot on your use case, but a 100ms to 1000ms delay is probably a good order of magnitude. However, when analyzing the meaning of such an alarm, be careful also about the Java garbage collector that blocks the JVM and may cause deadline violations.

The default value is -1 (disabled).

**Group period**

The execution engine periodically checks if the current number of virtual users matches the specified load profile: in case some virtual users are missing, new ones are instantiated; in case virtual users are too numerous, some of them are stopped once their current action is complete. Stopping virtual users before the normal completion of their behaviors is performed only if the “force stop” option has been enabled in the load profile definition. Otherwise, the execution engine will just wait for the population to naturally decrease as behaviors complete.

The population checking period is set in milliseconds:

- before runtime:
  - by setting system property `clif.isac.groupperiod`
  - or by adding option `groupperiod=my_custom_group_period_ms` to the “arguments” field;
- at runtime, by changing the value of parameter “groupperiod”.

The good period value is a trade-off between performance and accuracy of the engine: a short period will increase the engine overhead but the virtual users' population will be closer to the load profile specification. The default period (see appendix p. 35) is probably a good order of magnitude for common test cases.

**Scheduler period**

When a thread from the pool has just completed an action for a virtual user which is entering a think time period, it asks the engine for an action to do for another virtual user. If there is nothing to do at this time, the thread makes a small sleep before asking again, and so on until it gets something to do. The small sleep duration is given in milliseconds by the scheduler period parameter. This parameter may be changed:

- before runtime:
  - by setting system property `clif.isac.schedulerperiod`
  - or by adding option `schedulerperiod=my_custom_scheduler_period_ms` to the “arguments” field;
- at runtime, by changing the value of parameter “schedulerperiod”.

The good period value is a trade-off between engine reactiveness and performance. A zero value should be avoided since the threads waiting for something to do would enter a frenetic polling loop on interrogating the engine, which typically wastes all processing power. A big value should be avoided too for the sake of think times accuracy. The formula below gives the possible variation range of think times:

\[
\text{specified think time} \leq \text{actual think time} \leq \text{specified think time} + \text{scheduler period} + \text{context switching overhead}
\]

The default value (see appendix p. 35) seems to be a good value for common test cases. In the general case, you should ensure that: (1) the scheduler period is significantly less than the think
times, and (2) the scheduler period is significantly less than the job delay setting (when positive/enabled).

**Storage options**

As a CLIF load injector, the ISAC execution engine produces a number of events:

- one life-cycle event is produced each time the engine state changes: initializing, initialized, starting, running, suspended, etc. (refer to the CLIF Programmer's Guide for details about the blade life-cycle specification);
- one action event is produced for each request (aka sample) on the SUT;
- one alarm event may be generated each time a think time is actually longer than specified, according to the given tolerance threshold (see Job delay parameter described above).

These events are stored unless you specify not to do so, through the following parameters:

- `store-lifecycle-events`
- `store-action-events`
- `store-alarm-events`

Acceptable enabling values are: on yes true

Acceptable disabling values are: off no false

Disabling storage for an event type has the following advantages: increased ISAC engine power, reduced time for final data collection, reduced storage space. As a matter of fact, some test cases may generate gigabytes of data that may be too heavy to analyze. Moreover, high events throughputs (thousands of events per second) may overwhelm the disk transfer rate. The drawback of disabling event storage is that you won't keep any data for this event type on this injector.

A possible smart use of this feature is to disable action events storage for some massive load injectors (heavy background load), but to store and analyze the results from a couple of load injectors generating a light load. This way, you get a reduced amount of data, and data is quite accurate because the corresponding load injectors were far from saturating.

Note that disabling storage of life-cycle events and alarm events is possible but not recommended in common test cases:

- life-cycle events give an interesting and very lightweight trace of the injector's activity steps, whatever the test duration, with no noticeable impact on the engine performance;
- the occurrence of alarm events shows that something did wrong during the test, which is key to the test analysis, while no alarm event is generated when everything goes well.

As a conclusion, storage of life-cycle and alarm events is commonly always useful and never disturbing.

**Dynamic load profile change**

In case your scenario defines no load profile, or when you want to dynamically change the predefined load profile while a test is running, you can change parameter "population" of the ISAC execution engine. This parameter has the following form: \( b_1 = n_1; b_2 = n_2; ... \) where \( b_i \) is the name of a behavior in the ISAC scenario and \( n_j \) is the number of instances (aka virtual users) of this behavior.

When getting the current value of "population" parameter, if the current population is ruled by a specified load profile, you will get empty values: \( b_1 = ; b_2 = ; ... \) Since the population may change
accordingly to the load profile, no value is given. Once a population is set for a behavior, the population for this behavior becomes constant and the load profile for this behavior is definitively lost. As a result, the test will never complete by itself: you will have to stop it by yourself, at the moment that seems relevant for you.

Note that increasing a behavior's population through the setting of "population" parameter should be made carefully: all necessary new virtual users are created at once, and may result in a brutal load increase on your injector and SUT. Depending on the desired effect, it might be wise to add a linearly distributed random think time at the beginning of your behavior definition so that virtual users don't simultaneously start their actual load activity even though their are created at the same time. Of course, you must anticipate on this when writing the scenario.
